# Survey Background

## About the Community Assessment Survey for Older Adults™

The Indiana Family and Social Services Administration (IFSSA) contracted with National Research Center, Inc. (NRC) to conduct an assessment of the strengths and needs of its older residents. The Community Assessment Survey for Older Adults (CASOA™) is a statistically valid survey of older adults used by staff, elected officials and other stakeholders to plan for older adult services, programs and facilities. The ultimate goal of the assessment is to create an empowered community that supports a vibrant older adult population in the community.

The survey and its administration are standardized to assure high quality survey methods and comparable results across CASOA™ communities. Participating older adult households were selected at random and the household member who responded was selected without bias. Multiple mailings gave each household more than one prompt to participate with a self-addressed and postage paid envelope. Results were statistically weighted to reflect the proper demographic composition of older adults in the entire community.

Communities conducting CASOA™ can choose from a number of optional services to customize the reporting of survey results. IFSSA's Report Subgroup Comparisons is part of a larger project for the agency and the full report of results is available under separate cover.

One of the add-on options that IFSSA chose was to have crosstabulations of survey questions by the sixteen AAA service areas in Indiana, as well as respondent age, sex, household composition and income status. This report contains the results of these analyses.

### “Don't Know” Responses

On many of the questions in the survey respondents may answer “don't know.” The proportion of respondents giving this reply is shown in the full set of responses included in Appendix B of the full report. However, these responses have been removed from the analyses presented in this appendix. In other words, the tables display the responses from respondents who had an opinion about a specific item.

### Understanding the Tables

In this report, comparisons between demographic subgroups are shown. For most of the questions, we have shown only one number for each question. We have summarized responses to show only the proportion of respondents giving a certain answer; for example, the percent of respondents who rated the quality of life as “excellent” or “good,” or the percent of respondents who participated in an activity at least once.

The subgroup comparison tables contain the crosstabulations of survey questions by selected respondent characteristics. Chi-square or ANOVA tests of significance were applied to these breakdowns of survey questions. A “p-value” of 0.05 or less indicates that there is less than a 5% probability that differences observed between groups are due to chance; or in other words, a greater than 95% probability that the differences observed in the selected categories of the sample represent “real” differences among those populations. Statistical testing was not performed on multiple response questions (questions 8 and 17).

For each pair of subgroups that has a statistically significant difference, an upper case letter denoting significance is shown in the category with the larger column proportion. The letter denotes the category with the smaller column proportion from which it is statistically different. Differences were marked as statistically significant if the probability that the differences were due to chance alone were less than 5%. Categories were not used in comparisons when a column proportion was equal to zero or one.

Items that have no upper case letter denotation in their column and that are also not referred to in any other column were not statistically different.

It should be noted that when a table for a question that only permitted a single response does not total to exactly 100%, it is due to the common practice of percentages being rounded to the nearest whole number.

### Precision of Estimates

It is customary to describe the precision of estimates made from surveys by a “level of confidence” (or margin of error). A traditional level of confidence, and the one used here, is 95%. The margin of error for the IFSSA’s results overall was plus or minus 1% around any given percent for the entire sample (4,766 completed surveys). Where estimates are given for subgroups, they are less precise. Generally the 95% confidence interval is plus or minus 10 percentage points for samples of 100, and for smaller sample sizes (i.e., 50), the margin of error rises to plus or minus 14%. The significance testing for the following comparisons is more precise than the general rule of thumb. The 16 AAAs were tracked for comparison and the number of completed surveys for each are in the table below.

**Table 1: Area Agencies on Aging**

	Percent	Number
Area 1 - Northwest Indiana Community Action Corporation	10%	456
Area 2 - REAL Services, Inc.	7%	342
